it can be many characters that together comprise the token.

As the StringTokenizer class object moves its way through a String, it automatically knows where it is in the String, you do not have to keep track of that. When you instantiate an object of type StringTokenizer, you have three alternatives arguments for the Constructor

```
1.) String stringtobetokenized
2.) String stringtobetokenized,
String delimiter
3.) String stringtobetokenized,
String delimiter,
boolean returnTokens
Default delimiters: " \n, \t, \r "
Default returnTokens = false.
```

6.6.1 StringTokenizer Class: Methods

```
int         countTokens()
boolean     hasMoreTokens()
boolean     hasMoreElements()
Object            nextElement()
String            nextToken()
String             nextToken( String delimiter )
```

countTokens() method counts how many more times this tokenizer object's nextToken can be counted.

```
int countTokens()
```

It returns an integer with that number.

hasMoreTokens() simply tests if there are more tokens available from this tokenizer's String.

boolean hasMoreTokens() method if returns true, it anticipates that the a call to method nextToken() right after this would succeed in returning a token.

hasMoreElements() is used to override a method inherited from the Enumeration interface, which this class implements.

```
boolean hasMoreElements()
```

In effect, this does the same thing as the hasMoreTokens() method. true if there are more tokens.

nextToken() method is the workhorse. It gets the next token waiting in the String that was used to instantiate this object.
