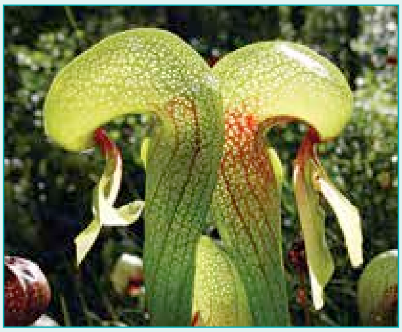
## Plants can be non vegetarian too, and have evolved a number of complex mechanisms to capture and kill insects, then subsequently process the nutrients to get a fitness advantage

**Aditya Madanapalle** | aditya@digit.in

This is a Heliamphora chimantensis with opened and closed "pitchers" which are specialised leaves that contain a mixture of water, nectar and digestive enzymes that attract and drown the insects. The traps in these pitcher plants are known as "pitfall" traps.



Darlingtonia californica or the cobra lily has a pitcher that mimics the appearance of a snake. instead of collecting rainwater, the liquid in the pitcher is maintained with water from the roots.

The golden bladderwort or Utricularia aurea belong to a group of plants with a sophisticated trapping mechanism that captures insects in a sac through a sudden release of water.

The Nepenthes jamban was formally described in 2006. This Sumatran pitcher grows from hanging tendrils, and has a flypaper like sticky surface in the toilet seat shaped bowls.

The Pinguicula conzattii is an example of a carnivorous plant with a flypaper trap. The sticky leaves of the plant have digestive glands that consume the captured insect where it is trapped.

The Drosera glanduligera has what is described as a catapult-flypaper trap, growing new sticky tendrils that permanently bend inwards after an unlucky insect has been caught.

Drosera capensis has leaves with sticky tentacles growing all over them that lure in insects with digestive secretions. The leaves then wrap around the captured insect before digesting it.
