```
    duplet (x, y, z);
    cout << "x=" << x << ", y=" << y << ", z="
<< z;
    return 0;
  }
```

```
      The output of this program is:

   x=4, y=14, z=18
```

Here, the main part is the declaration of the function `duplet`. The type of parameters passed are followed by `&`. This specifies that the arguments that are passed should be passed by reference and not by value, that is, we associate the variables `m`, `n` and `o` with the arguments passed to the function. This method of passing arguments by reference is different from that of passing arguments by address in C. While passing an argument by address, the process involves passing the address of the variable rather the variable itself. If the above program is written using the concept of passing arguments by address in C, then the program will be as follows:

```
  #include <iostream.h>
  void duplet(int* m, int* n, int* o)
  {
    *m*=2;
    *n*=2;
    *o*=2;
  }
  int main ()
  {
    int x=2, y=7, z=9;
    duplet (&x, &y, &z);
    cout << "x=" << x << ", y=" << y << ", z="
<< z;
    return 0;
  }
```
