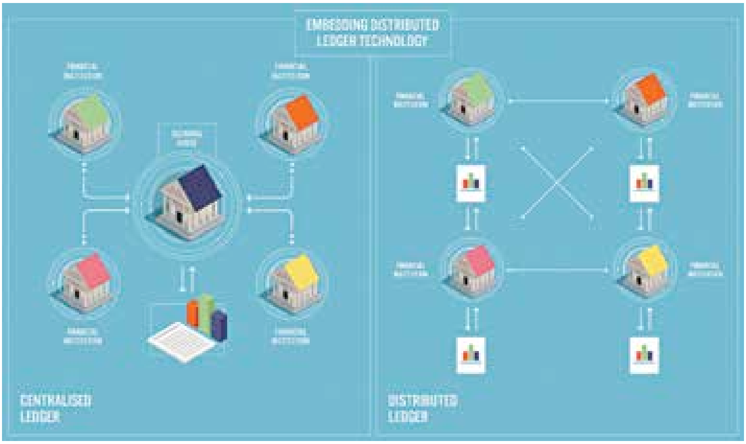
depends on the elected group. This method might go against the nature of blockchains, but it works brilliantly for security demanding operations like database management and auditing. Ideally, organisations should elect a diverse group of people who would not be influenced by each other



Differences between ledger systems

or common sources. This ensures that even if the management is small, it has a relatively higher stability. Private ledgers can even be set up for specific jobs or even specific projects. Due to a smaller management pool, the scalability of such ledgers is much more flexible than a public variant. Even the time to validate transactions is much faster due to the same reason. The closed nature also makes sure that this advantage of flexibility and speed does not dissolve.

Some widely known examples:

Monax and MultiChain are popular platforms to build organisation centric blockchains. Both try to simplify the process through comprehensive education tools and maintaining active communities. They even provide smart contract SDKs that come along with regulatory compliances. Most organisations prefer to customise their blockchains as per their needs.

Federated Ledgers

Very similar to the private variants, but instead of being based inside a single organisation, federated ledgers are for a wider reach. Even though
