```
>>> d[5] = 'Hercules'
>>> d
{1: 'David', 2: 'Goliath', 3: 'Judith', 4: 'Saul', 5: 'Her-
cules'}

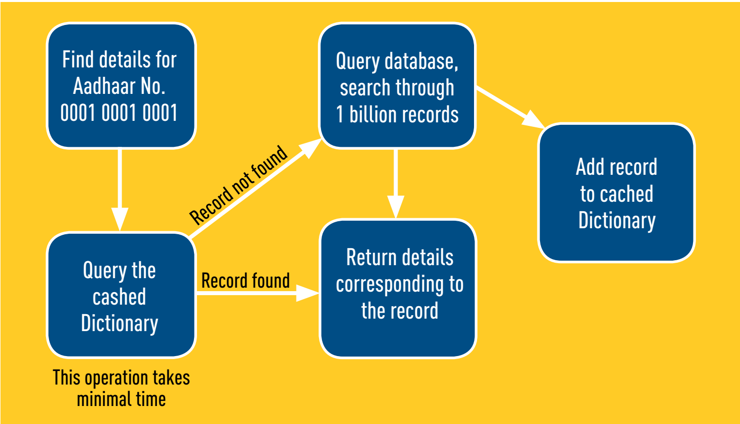
>>> d.update({1: 'Abner', 6: 'Josiah'})
>>> d
{1: 'Abner',2: 'Goliath',3: 'Judith',4: 'Saul',5: 'Hercules',
6: 'Josiah'}
```

- A deletion operation can be performed using the `'del'` operator or using the `pop()` method which is identical to the `list` data type.
- We can evaluate membership of keys using the in and not in operators. A `key`, if present in a dict returns a `True` for an `'in'` operation, `False` otherwise and vice versa for the `'not in'` operator.

```
    >>> 1 in d
True        #Since d contains the key (1)
```

Dictionary Usage

While implementing caches in an application, dict comes in as quite a handy data structure. Let's consider an example of the nationwide Aadhaar application, wherein we fetch the data of a person using his/her Aadhaar



How dict's can help us with real life scenarios?
