2. Basic Input and Output in C++

C++ offers libraries that enable us to perform input and output operations in the form of streams, which are sequences of bytes. The commonly used methods for taking input and printing output in C++ are cin and cout. These methods are fundamental for performing input and output operations in C++.

3. Comments in C++

Good documentation is essential for a programmer, and one way to achieve this is through comments. Comments are programmer-readable explanations or annotations added to the source code of a program. They are not executed by the compiler or interpreter, but serve to make the code more readable and aid in error finding.

4. Data Types and Modifiers in C++

In C++, variables are declared with a specific data type that restricts the type of data they can store. The purpose of data types is to inform the compiler about the type of data that will be stored in the variable. When a variable is declared, the compiler allocates memory for it based on the data type that was specified. Different data types require different amounts of memory. Data type modifiers can be used to adjust the amount of memory allocated for a particular data type. Proper use of data types and modifiers is important for efficient memory usage in a program.

5. Variables in C++

In C++, a variable is a name assigned to a specific memory location used to store data. It serves as the fundamental unit of storage in a program, and its value can be modified during program execution. Any action performed on the variable directly affects the memory location it represents. However, before using any variable in a program, it must be declared, indicating its data type and name.

6. Variable Scope in C++

In general, the scope is defined as the extent to which something can be worked with. In programming also the scope of a variable is defined as the extent of the program code within which the variable can be accessed or declared or worked with. There are mainly two types of variable scopes, Local and Global Variables.

7. Uninitialised variables in C++

Stroustrup has noted that the “zero-overhead rule” is one of the factors that
