
The steady and calculated production rate of Bitcoins maintains its value in the market.

Bitcoin as a decentralised digital currency

Many users of digital currencies, specially Bitcoin, express concerns relating to it being a fraudulent scheme designed to fool people into exchanging real currency for alpha-numeric sequences that have no actual value. But as we have observed value is generated through community trust in the system of the currency itself. The use of Bitcoins within the system doesn't assure any participant unfair gains or profits. The currency benefits from its decentralised nature which ensures that no individual or institution is at the core of it and positioned to unfairly benefit from its use.

The Bitcoin system is based on early low reward efforts leading to long term community benefits. The first persons to mine for Bitcoins were not at a significant advantage as the value of Bitcoins at the time was negligible or close to 10,000 BTC for a pizza (we don't know which one). At todays rates just 1 BTC would easily purchase 100 pizzas. But for the system to be functional in the early days the Bitcoins needed to be used in transactions that didn't value the Bitcoins very highly - a reflection of its nascent trustworthiness.

There was no government or agency that could artificially increase the value of the Bitcoin due to its decentralised nature. The value had to evolve from continuous usage and proliferation of the user network both in the digital as well as real world. Bitcoins are now accepted in over one thousand locations across the world including real world locations such as cafes and restaurants.

Another unique aspect of this decentralised nature is that unlike other fiat currencies, Bitcoin isn't an inflationary currency with its value being
