```
Employee. earnings (name);
```

In the above statement, the employee is regarded as the object, earnings as the message, and name as the information.

In addition, the following needs to be mentioned:

- **Data Abstraction and Encapsulation**
- **Inheritance**
- **Polymorphism**

1.2 Data Abstraction And Encapsulation

Data abstraction and Encapsulation are fundamental to OOP. The process of wrapping up data and functions into a single unit is called 'encapsulation'. In other words, encapsulation hides the functional details of a class from objects that send messages to it. Data is not generally accessible to the outside class and only functions wrapped in the class can access it. Encapsulation is also achieved by specifying the particular class using objects of another class.

Abstraction refers to the act of representing essential features and characteristics without detail. Classes use the concept of data abstraction and are known as 'Abstract Data Types'.

1.3 Inheritance

This is another important feature of OOP. By Inheritance, classes can acquire the properties and methods of another class or classes. Inheritance supports hierarchical classification. In other words, the process by which the subclasses inherit the attributes and behaviour of the parent class is termed as 'Inheritance'.

For instance, the class 'Dog' may have sub-classes as Spitz,
