```
            Square q1 ;
//here the first Constructor without any argument

is invoked
            cout << "\n First Square----------'\n"
;
            q1.Insert_Ib() ;
            q1.View_area() ;
            cout << "\n\n Second Square---------
'\n" ;
            Square q2 (5.6, 3.5) ;
    //here the second Constructor with two

arguments is invoked
            q2.View_area() ;
  }
```

```
   The output of this program is:

   First Square---------'

            Insert the span of the Square:    4
            Insert the breadth of the Square:5

            The area of the Square = 20

   Second Square-------'
            The area of the Square = 19.6
```

Another type of constructor is a copy constructor. Let us look at the form of the copy constructor:

```
class name (class name &).
```

While initialising an instance, the copy constructor is used by the compiler. Here, the values of the other instance of the same type are used.
