words. The majority of function statements that are used create a stronger bond between the identifier – i.e the name of the function and the code which is used within the method body. However the value of the variable can be changed by using an assignment statement and at the same time the link or connection between a function expression and a variable can also be severed. To cope with this problem, the programmer can declare the variable as a constant, but this makes the code harder to read and prevents the use of the override and final keywords.

Return Values From Functions

A function can return a value by the use of the return statement, followed by that particular value or expression that the programmer wants to return. This can be demonstrated with the help of the following example:

```
function doubleNum1(baseNumber:int):int
{
    return (baseNumber * 2);
}
```

It is to be noted that a function is terminated by using a return statement. This ensures that all statements which lie below the return statement will not be executed. This can be shown by an example given below.

```
function doubleNum(baseNum1:int):int {
    return (baseNum1 * 2);
    trace("after return"); // This trace statement will not be executed.
}
```

In the case of a strict mode, the value that is returned by the function should match the specific return type that is selected by the programmer. This can be demonstrated with the help of the example shown below; this generates an error in strict mode as the function does not return a valid value.
