mathematical and logical computations to be performed on operands. In essence, operators operate on the operands. The functionality of the Java programming language would be incomplete without the use of operators.

8. Decision making: In Java programming, decision-making or control statements function similarly to decision-making in real-life situations. In programming, we often encounter situations where we want a specific block of code to execute only when certain conditions are met. Control statements are used in programming languages to manage the flow of execution based on specific conditions. These statements help to advance and branch the flow of execution based on the program's state changes.
9. Looping: Looping in programming languages is a feature that enables the repetitive execution of a set of instructions or functions as long as a certain condition remains true. Java offers three ways to execute loops. Although these methods provide similar basic functionality, their syntax and condition-checking time differ. For more information on loops in Java, see the following resource: Loops in Java.

JVM Architecture

In Java programming, the Java Virtual Machine (JVM) serves as the runtime engine for executing Java applications. It is responsible for invoking the main method within a Java code. JVM is a vital component of the Java Runtime Environment (JRE).

Java applications are commonly referred to as WORA, or "Write Once Run Anywhere." This means that a programmer can develop Java code on one system and expect it to run on any other Java-enabled system without requiring any
