```
  // myHandler() is declared later in this app.
}

// loop() runs continuously, it's our infinite loop. In this program we only want to repsond to events, so loop can be empty.
void loop() {

}

// Now for the myHandler function, which is called when the Particle cloud tells us that our email event is published.
void myHandler(const char *event, const char *data)
{
  /* Particle.subscribe handlers are void functions, which means they don't return anything.
  They take two variables-- the name of your event, and any data that goes along with your event.
  In this case, the event will be "buddy_unique_event_name" and the data will be "on" or "off"
  */

  if (strcmp(data,"led-off")==0) {
    // if subject line of email is "off"
    digitalWrite(led,LOW);
    digitalWrite(boardLed,LOW);
  }
  else if (strcmp(data,"led-on")==0) {
    // if subject line of email is "on"
    digitalWrite(led,HIGH);
    digitalWrite(boardLed,HIGH);
  }
}
```

With this, you'll have a working app that responds and outputs based on user interactions. There's a whole lot you can do with Raspberry Pi that should be taken up after mastering the basics discussed in this chapter. d
