```
x = 0;
System.out.println( "\n 2nd Baseline, x = " + x );
System.out.println( "\n Post-increment = x++ = " + x++
);
System.out.println( "\n After increment, x = " + x );
System.exit( 0 );
}
}
Baseline, x = 0
Pre-increment = ++x = 1
After increment, x = 1
2nd Baseline, x = 0
Post-increment = x++ = 0
After increment, x = 1
```

2.3 Logical operators

So far, all of the conditions we have tested were simple. It is possible to construct complex conditions using the Java Logical Operators, which—again—were inherited form C/C++.

```
&&      Logical AND
||      Logical OR
!       Logical NOT
```

2.3.1 Logical AND

```
if( gender == 'F' && age >= 65 )
```

Condition is true only if both halves are true. Java will short-circuit the process—skipping the 2nd half of the expression—if the first half is false.

2.3.2 Logical OR

```
if( gender == 'F' || age >= 65 )
```

Entire condition is true if either half is true.

2.3.3 Logical NOT

```
if( !(age <= 65) )
```

Negates the expression—not many opportunities to use.

2.3.4 Logical Boolean AND
