changes to the material and texture by using the following code:

```
Texture.Sampler sampler =
        Texture.Sampler.builder()
                .setMinFilter(Texture.Sampler.Min-
Filter.LINEAR)
                .setWrapMode(Texture.Sampler.WrapMode.
REPEAT)
                .build();
// R.drawable.custom _ texture is a .png file in src/
main/res/drawable
Texture.builder()
        .setSource(this, R.drawable.custom _ texture)
        .setSampler(sampler)
        .build()
        .thenAccept(texture -> {
          arSceneView.getPlaneRenderer()
                  .getMaterial().thenAccept(material ->
                  material.setTexture(PlaneRenderer.
MATERIAL _ TEXTURE, texture));
        });
```

For working on the shadows, use the renderer function to give some depth to the scene and to make it appear a little more life-like. There are several objects in Sceneform that can cast shadows and objects that are programmed to receive shadows.

By default, the system has shadow casting enabled. Call setShadow-CastingEnabled() to turn it on. Then finally input the following sample code to trace the scene:

* Create an AR scene that tracks planes. Clicking on a plane places a 3D Object on that spot.

```
*/

@Override

public void onRendererStart() {

// Create the 3d ar scene, and display the point
clouds.
```
