```
}
```

```
The code block in image1 starting with transform specifies that the transform property will be a Rotation through -90 degrees, which is anti-clockwise, about the z-axis running through the center of the image at (75,75), since the image is 150 x 150 pixels.
```

The other transformation available is Translate. This produces a change in position of the item. Also note that the order of the transformations is important.

Animations

Animation in QML is done by animating properties of objects. In QML these are QML Basic Types named as real, int, color, rect, point, size, and vector3d. There are a number of different ways to do animation. Here we will look at a few of them.

Number Animation

Previously we have used a rotation transformation to change the orientation of an image. We could easily animate this rotation so that instead of a straight rotation counter-clockwise of 90 degrees we could rotate the image through a full 360 degrees in an animation. The axis of rotation won't change, the position of the center of the image will not change, only the angle will change. Therefore, a NumberAnimation of a rotation's angle should be enough for the task.

If we wish for a simple rotation about the center of the image then we can use the rotation property that is inherited from Item. The rotation property is a real number that specifies the angle in a clockwise direction for the rotation of the object.

Here is the code for our animated rotating image.

```
import QtQuick 1.0

Rectangle {
     id: mainRec
     width:  600
     height: 400
     Image {
```
