consumed by miners is usually the amount that could help power a relatively medium sized town. Add to this the fact that there is specialised equipment for mining that comes at a cost.

Given that blockchains like bitcoin want to avoid a 51% attack, they will create excessive number of miners to ensure that a mining majority of nodes/individuals does not exist. A majority attack or 51% attack can be possible only if majority of the computing needs of a network come from a single/singular group of providers, who then control the hashrate of the blockchain. This could give them the power to indulge in unlawful mining which would eventually lead to unsolicited double spends.

What this means in simple terms for blockchain is that if the price of electricity were to drastically increase in the years to come, very few companies or groups would be able to afford mining. This would put them at the risk of being controlled and dominated by said groups and open themselves up to the possibility of majority attacks and double spends on a regular basis.

Open To External Attacks:

Blockchain is based on a large network of nodes. These nodes have the same information stored on them. This would mean that the information, even if

Having open nodes also leaves room for hackers to infiltrate networks
