try and understand even more clearly what the problem is and how blockchain intends to solve it.

Why blockchain?

As the internet-of-things continues to grow at a rapid rate, sensors and devices are becoming more commonplace to communicate information in business networks for data such as location, temperature and other properties that need to be shared. A private blockchain ledger can help create a tamper-free record. This opens up new ways of automating business processes among partners without setting up a costly centralized IT infrastructure and all participants have access to the same data. Let’s look at how supply chain benefits when data is shared.

The private blockchain passes through all the multiple carriers in the supply chain. The business contract specifies the conditions that must be met during the shipment from the factory to the grocery store and all parties must adhere to the terms of the contract. A temperature sensor embedded in the package stores the data locally and sends it to the data cloud. The cloud information is shared across all peers. After every carrier meets the contractual obligations, the shipment arrived its final destination without exposure to excess temperatures.

‘Blockchain eliminates the need for any third party vendors and is a direct transaction between the producer and the buyer’
