

Kernel errors, music CDs that won't play, blurry monitors, troublesome Linux installations and other grievances that need a fix

Software

Kernel error

Q I am using a Compaq system with 256 MB of RAM and a 433 MHz processor. Recently when I started my system I got an error, which says 'Error loading kernel. You must reinstall Windows.' Please help me.

Saurabh

Via e-mail

A The reason you're receiving this error is because the Kernel32.dll file is missing or is damaged. To resolve this problem you will have to extract a new copy of the Kernel32.dll file from your original Windows CD-ROM. To do so, follow these steps:

Restart your computer, press and hold down the [Ctrl] key while your computer restarts until you see the Windows 98 Start up menu, and then choose 'Command Prompt Only'. If you are using Windows Millennium Edition (Me), start your computer with the Windows Me start up disk.

Type the following commands, pressing [Enter] after each line:

```
cd \windows\system
```

```
ren kernel32.dll kernel32.xxx
```

Extract a new copy of the

Kernel32.dll file from your original Windows disks or CD-ROM to the **Windows\System** folder.

Restart your computer once again and you should be able to boot without any errors.

Cannot view inserted images in WinWord

Q I recently upgraded my operating system to Windows XP and my Office 2000 package to Office XP. Previously I could place images in the WinWord program, but when I try to insert images now, only a thick black border appears. However, I can insert images in all the other programs of Office XP and they appear fine. I uninstalled and reinstalled Office XP but the

Uncheck the option of place holders to view your images

result is the same. Please solve my problem.

Sanjay

Via e-mail

A You need not reinstall Office XP. All you need to do is open the WinWord program, and go to **Tools >**

Options > Picture Placeholders.

Uncheck this option and you will now be able to view the inserted images in the document.

Can't upgrade to XP

Q I am using Windows Me as my operating system. But

Installing the Penguin

Q I use a Pentium III processor with Windows 98 as the operating system. I have only one primary drive (C:\), 64 MB RAM and a 20 GB hard disk. Now, I want to install Red Hat Linux 7.1 on my PC. I am confused about it as some people suggested that I install it with the help of Partition Magic. Will I need to format my primary drive completely or can I simply install it. Please suggest an easy way to install Linux.

Jinal

A To install Linux on your machine you will require some unformatted space; only then will you be able to install it. You can create unformatted space (i.e. by creating a partition) through Fdisk or any third-party tool such as FIPS. After doing that boot through the Linux CD and install it in the unformatted space. That will do it and you don't have to worry about formatting your primary partition for it.
