A This occurs if Windows Setup does not delete all of the files in the **WinDir\System32\Catroot2** folder while removing the earlier version of Windows. WinDir is the Windows installation folder. To work around this error, manually delete any files that remain in the **WinDir\System32\Catroot2** folder.

This error can also cause your machine to restart constantly and if this is the case and you cannot use the interface to clear the Catroot2 folder, you must delete the files from a command prompt.

To gain access to a command prompt, start the computer either from a Windows 98 or Windows Me boot disk, or from the Windows XP CD-ROM. At the command prompt, type **cd\windows\system32\catroot2**, and then press [Enter]. Type **del *.*** and then press [Enter] to clear the Catroot2 directory. Now try installing Windows XP and it should work fine.

A sound problem

Q When I use Windows Media Player to play high-quality video or a DVD, the audio quality is extremely poor, and sometimes garbled. Strangely, this does not occur with lower quality video. Why is this so?

Ravi

Via e-mail

A This happens if you use NeoMagic video adapter drivers. Some of the NeoMagic

MP3 songs refuse to play

Q I have a huge stack of MP3 songs on my hard disk. Since I recently purchased a music system capable of playing MP3s, I decided to burn them on a CD so that I can play them on my system and also free some hard disk space. After burning them I found that my music system couldn't play them. However,

when I inserted the same disc in my computer it plays fine. Is my music system defective? Please help me.

Parag

Via e-mail

A No, your music system is not defective. The reason it is not playing your MP3 CD is because you have probably burnt the CD at an extremely high rate. Burnt it again at a speed of 4x and it should play without a problem on your player.

video adapter drivers are not fully compatible with Windows XP. Note that this issue can also occur with other video adapter drivers that are not fully compatible with Windows XP. To work around this issue, try either or both of the following methods:

- Reduce video hardware acceleration in Windows Media Player. To do this, in Windows Media Player, click 'Options' on the 'Tools' menu. Click the 'Performance' tab. Under 'Video Acceleration', move the slider closer to 'None' and then click 'OK'. Note, however, that this procedure may cause poor video performance.
- Alter the Display Settings. To do this, click on 'Start', and then 'Control Panel'. Double-click 'Appearance and Themes', and then double-click 'Display'. Click the 'Settings' tab. Click '16-bit, 24-bit, or 32-bit colour quality'. Click 'OK'.

Now you shouldn't face this problem any more.

No path found

Q I am using Windows XP. Of late, whenever I try to open any program I keep getting this error: 'The specific path does not exist. Check the path and try again.' Now I am unable to open any program.

Help required urgently.

A It seems your machine is infected with the SirCam virus because of which you are getting this error. You can go to **www.pandasoftware.com** and download the removal tool from the Web site. Running this tool will remove all traces of the virus and you should not receive this error again.

Error Checking command

Q My problem is that when I enter a formula error such as 'divide by zero' into a spreadsheet cell in MS Excel, the Error Checking Smart Tag (the floating command and message box) does not appear as expected. Also, the Error Checking command is not available on the 'Tools' menu. Why does this happen?

Vikas

Via e-mail

Enable Error Checking in Microsoft Excel

A This problem occurs because Error Checking is not available when a workbook is protected or shared. To solve this problem, unshare or unprotect your workbook. (You will find the necessary options in the 'Tools' menu).

Blebla attacks

Q I have a Pentium III 800 MHz system with 128 MB RAM, and a 20 GB hard disk. Whenever I access a file with extension JPEG, BMP, EXL or DOC, it gets converted into a '.exe'. While scanning my PC with Norton Antivirus 2001, a message was displayed, 'Unable to repair the file c:\windows\sysrnj.exe. It is still infected with the W32.Blebla.B.Worm virus.' After I quarantined this file I have been unable to run any program and it displays a message, 'Windows cannot find sysrnj.exe file'. How can I solve this problem?

A W32.Blebla.B.

Worm is an update of the W32.Blebla worm. It usually arrives in an e-mail that has an HTML body and two attachments. When you read the message, the two attachments are automatically saved and launched.
