

features ■ technology next

With full GPRS support, this device doubles as a cellular device. It also integrates Bluetooth for wireless connectivity at your office or airport!

The 240x320 touchscreen displays 65,536 colours and is transreflective, meaning that you can view it in daylight with the same ease as in total darkness

Powered by a 400 MHz XScale processor and 64 MB of RAM, this handheld has what it takes to crunch through your applications

Power that Lasts

With all that increased processing power, bigger and brighter screens and increased storage, the new-generation mobile devices need enough juice to survive on the road. Intel's Baniya, expected to surface in the first quarter of 2003, is one of the many technologies that strive to minimise the power usage of these mobile devices.

Mobile processors based on Baniya are capable of dynamically altering their clock speed depending upon the application. A process called Advanced Clock Gating implements power conservation by shutting off unneeded sections of the processor core, even when the rest of the processor is in operation.

Besides optimised power consumption, Baniya also intends to include dual-band 802.11a and 802.11b chipsets for facilitating wireless LAN support. Capable of running Windows XP and Windows 2000,

mobile computers using Baniya processors will consume a watt of power and have a battery life of between 3.5 to 4.5 hours for machines with 14 to 15-inch screens.

There is also a low voltage (LV) version of the chip that will be used on sub-notebooks and tablet PCs and will consume just half a watt of power. One chipset running these processors is codenamed Odem. It features DDR 266 support and is expected to be released in early 2003. Another chipset supporting Baniya is codenamed Montara GM and will be targeted at mini notebooks, sub-notebooks and tablet PCs.

These chips will feature a minimal number of interface points for easy integration. The first Baniya chips will appear in the first quarter of 2003 and will offer speeds of 1.4 GHz, 1.5 GHz and 1.6 GHz, using the Odem chipset.

devices to use Intel's new XScale processor. Running at a speed of 400 MHz, this handheld device has everything you would need—applications, communication and mobile entertainment. By integrating GPRS support for high-speed mobile connectivity, it's also Bluetooth capable, enabling you to tap into your office network, without being tethered to your desk. It can even be hooked up to your laptop or mobile phone for enhanced wireless connectivity. And yes, its processing power lets you watch movies right off the Web with TV-quality imaging!

Another interesting device is the Sony Clie PEG-NR70V, which features a compact QWERTY keyboard as a part of its flip-screen design. With a 320x240 resolution, 16-bit colour screen and audio support, this device runs the Palm OS. Most importantly, its functionality can be supplemented with a host of other devices such as a digital cam and MP3s that can be stored on Memory Sticks.

Phones get smarter

Using the existing cell phones, you can already access services such as WAP and SMS-based movie schedules that other service providers offer. But what if you could even book your favourite movie through your cell phone itself? Or even finding directions to the nearest theatre? Followed by recommendation for a good North Indian restaurant close

When they first arrived on the scene about five years ago, mobile phones served a single purpose: to keep you connected to the rest of the world via voice. Today, with enhancements in processing power and wireless technology, mobile phones are no longer restricted to voice; they can transfer data through Short Messaging Service (SMS) and with large, colour displays that are touch screen capable, broadband Internet access and robust processing power, the new

With full MP3 support, the Fujitsu-Siemens SX45 handheld even sports GPRS for cellular connectivity
