

Your Internet, My Internet

Every day, people type in an incorrect Web address around 20 million times, and consequently stare at an unexpected Web site or an error message. This fact was turned into an advantage by Verisign, the company maintaining the database of most of the .net and .com addresses on the Internet. It launched its Site

Finder service that is designed to redirect people making typos directly to a suggested Web site, which in turn, pays Verisign to do so.

Critics, including Yahoo!, AOL and MSN, are unhappy about loosing their prospective pay-per-click customers who use their respective search engines.

Microsoft's opening up

Microsoft has submitted the Video compression code of Windows Media Player 9 (WMP9) to the Society of Motion Picture Television Engineers. Having launched WMP9 a year ago with great fanfare, it finds itself competing against the MPEG-2 compression stan-

dard that the cable, satellite and video-editing fraternities have adopted with open arms. Rivals such as RealNetworks have stolen a march on Microsoft by sharing source code with the developer community, hence ensuring a steady support in terms of applications for more sophisticated cellular phones.

Super fast coax cable

Teleste and Essent Kabelcom, two European companies are working on a fast IP-based data access technology called Ethernet to the Home (ETTH), which offers speeds of up to 10 Mbps for residential customers, and upto 50 Mbps to business customers. Since it uses co-axial cables, no upgrade of infrastructure is required. Secondly, subscribers don't need additional equipment since it is based on Ethernet. The first trial is scheduled to take place in Netherlands.

The present alternatives to this technology are DSL and Cable Internet, but their maximum speed is just 8 Mbps. Another option is VDSL (Very High Data Digital Subscriber Line)—a variation of DSL—that offers a speed of 56 Kbps, but is valid for a limited distance. ETTH doesn't have this limitation, as it uses network amplifiers.

Old Bugs Revisited

The worm called Swen-A (aka Gibe-F), appears as a Windows security update. It exploits the vulnerability of Outlook and Outlook Express to execute automatically when the message is pre-viewed. The worm pops up a message posing as an update from Microsoft, asking whether you would like to install the security update, but effects the system regardless of your choice. It attempts to kill anti-virus programs and RegEdit. Visit <http://securityresponse.symantec.com/avcenter/venc/data/w32.swen.a@mm.html> for further details.

BAT.Deav.Worm

BAT.Deav.Worm is a worm that propagates through File sharing networks such as KaZaA and iMesh. When the worm is executed, it deletes files with .exe, .dll, .dat and .ini extensions. It then copies itself into your file-sharing software's shared folders under various file names for propagation. Later, it deletes all files with the extensions .doc or .zip, from your C: drive and proceeds to shut down Windows. Visit <http://securityresponse.symantec.com/avcenter/venc/data/bat.deav.worm.html> for a removal tool.
