Display Technologies>>

Getting a cheap, flexible electronic display is one of the major challenges that labs around the world are trying to meet. This will save a lot of space and allow for easy mobility. This has been achieved to an extent using LCD technology, but right now only monochrome displays are possible, not great looking HD displays that is the rage right now. 3D and holographic displays have been in the works for a long time, and will probably be a long time coming. 3D requires a lot of efforts on the production front, as well as glasses. Current Holographic technologies involve large spinning mirrors that occupy more space than the hologram itself. What you will be seeing around are portable and immersive entertainment systems such as the MYVU crystal ev.

Input Technologies>>

There are a bunch of major trends when it comes to input technologies. Roll up keyboards are passe, the rage now is flexible, water-proof and food-proof keyboards, that are pretty lightweight. Ultra-portability is achieved by pen-sized projectors that can throw out a keyboard on almost any surface, and these are already on the market. Touchable surfaces with tactile feedback is another area of focus. Be prepared for inputs to invade all kinds of surfaces, from tables, toll booths, advertisements in newspapers, even the roads are not ruled out. The sky is however, the limit, which will probably be saved up for displaying the tweets you send in about the food in a restaurant using a digital napkin. Wires will soon be stone-age technology.
