

■ Processor

The processor in the stylus keeps track of the pressure levels, the tools being and the also the switches. It gets this information and sends back this information through the modulator.

■ Switches

The switches are basically the left and right-click buttons. They are used to control the brushes in a typical painting software and also with the operating system

■ Magnetic panel

This is the one of the key components which generates the field and is connected to your PC. The field both helps generate power within the Stylus and also helps in tracking the location of the stylus. Newer models from Wacom allow touch using multiple fingers as well.
