Popular and open source email client Mozilla Thunderbird 3 gets ready to launch

Change at Ubuntu

Canonical CEO Mark Shuttleworth to step down

Recently, I removed a virus called killvirus.vbs using USB Disk Security and Threat Fire. Even then, a message keeps coming when Windows starts saying Could not find the script file killvirus.vbs. I want to get rid of that pesky message.

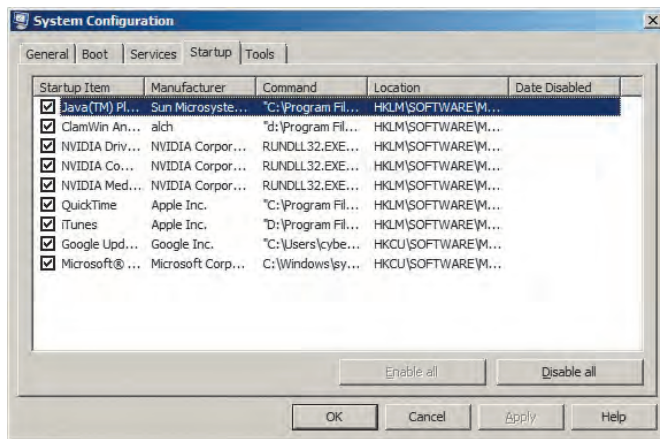

Avash Bista

One of the solutions might be to format your hard drive and install Windows altogether. Using System Restore

BIOS update for booting into BIOS

My motherboard is Micro Star Model No: MS-6577 Ver: 4.1. My current BIOS is Phoenix Award BIOS v6.00PG through which I cannot boot from neither bootable DVD nor USB drive. How can I upgrade my BIOS so that I can do the above and if possible, run a SATA Hard Disk as primary master Hard Disk using a SATA to USB cable.

Parnold

Disable any suspicious programs from loading during startup

to uninstall drivers isn't the best way to fix the issue. The wrong graphics card details might also be because of corrupted drivers. If possible, try installing your graphics on another system and check for similar errors. In case they are similar, you have to get the card repaired or replaced.

To get rid of the error message, go to Registry Editor by clicking on Start > Run and typing regedit. Browse to HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run and look for an entry for Killvirus.vbs. Delete any relevant entry you may find. You can also start MSConfig and disable the entry under the Startup tab.

Not all boards support booting through USB and very few had the feature added through a BIOS update. You have to first identify the exact model number of your motherboard and then look for the BIOS updates on the MSI web site. Look for the list of changes to find the USB boot feature. Most newer boards will let you select a USB device as a primary boot disk.

Long list

I have a long list of problems. My PC configuration is as follows. Operating system: Windows XP Pro SP 2, Memory: 512 MB DDR2, Hard disk: 80 GB, Processor: Intel Pentium 4, Motherboard: ASUS P5GD1-TM Series Rev.105.01.

1) My PC is infected with Autoit.VQV. It has created a folder within a folder (eg. folder name "New folder" with a file "New folder.exe" is present of capacity of at least 300 KB in every folder in the PC). Please suggest good anti-virus to remove this virus. I had to format my C partition, but it didn't help. This virus uses up a lot of space on my drive.

I can't install anti-virus such as Avast, Kaspersky or Norton. It gives me error messages. When I double-click on the installer, nothing happens.

2) Before formatting, I could play games such as *GTA San Andreas*, *Max Payne 2*, *Half-Life*, and *Soldier of Fortune* which are installed on the D partition. After formatting, my games can't find their folders so I delete their folders by pressing [Shift] + [Del] and then reinstall them. But I can't play them when I double click the game executables.

3) I can't play games such as *GTA Vice City* and *GTA Myraid Island*. It gives me a Unhandle Exception : c0000005 At address : 006f6330 error message. All these games mentioned work fine on my friend's computer.

4) I can't install Nero 8, but Nero 5 works. When I double-click on it, Nero extracts some files but gives me a MSI engine cannot updated, Please update manually message. I also can't install Adobe Photoshop CS4 because when I double-click on it, nothing happens. I can't install Bittorrent, but I can install uTorrent. It gives me some error messages.

5) My DVD drive can't read any of your DVDs (When I insert your DVDs it doesn't display anything). I have to boot several times, but it can

read some of my blank DVDs/CDs or DVDs written on my PC.

6) My CPU is also making a lot of noise.

All software/games mentioned worked properly before formatting the C partition. I kept my user name and password same. Please help me guys as I don't want to format my entire drive.

Abhishek Gupta

Most viruses will disable the task manager and registry editor. Some of them won't let you install anti-virus programs or even update them. You can try using online web scanners to stop of these problems, then install an anti-virus.

If you formatted the C drive, then the saved games folders from the Documents and Settings folders might have also been erased. The game crash also is because of some kind of corruption. Try reinstalling the game. The MSI engine error might be because you're using an older version of the Microsoft Windows installer application. Update it from Microsoft's site.

Try using a different DVD drive to read our discs. There might be a compatibility issue with the drive. Look for any firmware updates on the manufacturer's web site. The PC might be making noise because of either a faulty fan on the SMPS or the processor or graphics card.

If you have a poor quality cabinet, the panels on the sides or the base might be making the sound you're hearing. Do a thorough cleanup of the interiors and put some padding to reduce any vibrations.

A clean format and reinstall is also recommended. Try and use a different system to clear any viruses or worms on the remaining partitions before you do so. **d**
