

items to the Products_Archive table by setting the Criteria cell for the Discontinued field to =-1.

3. After appending the records to the archive table, you will need to remove them from the original table. Create a delete query with the same criteria you specified in the append query. If you create an append query that prompts for a parameter, you should also create a delete query that prompts for the same parameter. Make sure you enter the same values each time you are prompted when you run the queries. For example, create a delete query called Products_Delete using the same criteria as the Products_Append query.

4. Create a macro that first runs the append query and then runs the delete query. For example, create a macro called Products_Archive_Records that uses the OpenQuery action to run the Products_Append query and then uses the OpenQuery action to run the Products_Delete query.

5. Run the archive macro each time you want to archive your records. For example, run the Products_Archive_Records macro each time you want to archive discontinued products from the Products table to the Products_Archive table.

Lock for .ldb

Sometimes when a new user tries to access a shared database on the server, a situation arises causing Access to delete the .ldb file,

Bet you didn't know

Add Stripe Patterns to a Table in MS Word

One way to modify the built-in table formats that come with Microsoft Word is to apply your own stripe patterns. You can select the number of rows or columns to include in a stripe pattern and apply your colour choices to the pattern.

When you modify a table style, all tables with that style in the active document will be changed.

1. To add stripe patterns to a table, select the table.
2. Open the Styles and Formatting task pane from the 'Format' toolbar.
3. In the Styles and Formatting task pane, click the arrow on the 'Table style', and then click 'Modify'.
4. In the 'Apply Formatting to' box, select a stripe pattern by doing one or both of the following: Add stripes to rows, Click Odd row stripes or Even Row stripes.
5. To select a colour for the stripes, click the arrow next to Shading Colour, and then chose a colour.
6. By default, the stripe patterns are applied to every alternate row or column.
7. To change the number of rows or columns in a stripe pattern, click Format, and then click Stripes.
8. Change the number of rows in a stripe or the number of rows in a row band box.

but because of another user also working on the file, the .ldb files fail to get erased. This is tried 15 times before Access fails and gives up. This process causes a performance hit.

To overcome this problem you need to create a form on the client side, which creates a

persistent connection with the database by opening a recordset. To do this:

1. Create an empty form.
2. In the code view, declare a **recordset** variable in the global declarations section.
3. In the OnOpen event, open a recordset against any table.
4. In the OnClose event, which will activate when the MDB is closed, close the recordset and set the variable to nothing.

5. Ensure that you always open this form when opening the MDB.

Maintaining persistent connections to linked tables could improve performance significantly because it prevents Microsoft Jet from constantly deleting, creating, and obtaining locking information from the other database's locking information file.

Open Database Objects Faster

If a database has the Name AutoCorrect feature enabled, more often than not, users will experience a delay when they try to open any of the database objects. When using a secured database with Name AutoCorrect enabled, the current user must have design permissions on the object to enable Name AutoCorrect to track, fix, and log the binding errors when an object is opened. If a user does not have design permission on an object that Name AutoCorrect is trying to change, the changes occur every time that the user opens the object. This happens because the user does

not have permissions to ever save the changes.

To fix this, open the Tools menu, select Options, and choose the General tab. Then, clear the Track name AutoCorrect check box.

Query based on User Input

Access allows you to enter parametric queries. Such queries can accept inputs from the user, while running to make the query result conditional, based on the user input. They are useful because the query itself does not need to be modified by the query designer. You can easily add conditions to the query by using the 'Criteria' box of the Query Designer grid. Enter some text to describe the input enclosed square brackets in the criteria box query_pmt.bmp. Next time you run the query, Access will ask you for the input of the field to complete the query on the fly.

Defining the order of user inputs

You can make your query more complex. Example, you may set the Between...And... operator by entering something like "Between [min age] And [max age]" in the same criteria box.

If you have parametric
