

# Building A Web Page Using NoteTab Pro

Learn about one of the easiest ways to build Web sites—both, for beginners and experts alike...

Varun Dubey

If you are trying to learn HTML, or are new to building Web pages, we have just the thing for you! In fact, even if you find HTML easy enough to do it in your sleep, you should still go through this workshop—the software we're talking about here will let you update your pages so quickly that you'll need to work while you're awake as well!

The options this software offers are so many, a full book could be dedicated to it. Here, we'll walk you through some of the features and leave you to explore and play with the software yourself.

## What you need

The software you need is called NoteTab Pro. It can be downloaded from [www.notetab.com](http://www.notetab.com). You can try it free for 30 days, after which it costs \$19.95 (Rs 870).

## 1 Easy Interface

Once you start the software, you will be presented with an interface that looks like a cross between Microsoft Word, Opera and Explorer. You have formatting buttons on the top, the various options (such as HTML, CSS etc.) at the bottom, and what's more, you can open multiple files in different tabs just like Firefox—the best of all worlds!

NoteTab's Default Screen

## 2 Writing The Code

To create HTML, select 'HTML' from the drop-down menu on

the left, or from one of the tabs at the bottom. The options and commands in the left pane will change accordingly.

To start creating a Web page, click on 'New Web Page' on the left, and

Set the text and link properties using this window

you'll be presented with a template wizard that will let you select the basic properties of the page—such as the title, description, keywords, etc. Once you're done with that, you will be presented with another window that will allow you to set things such as the background colour, text colour, link colours and more. You can even include a background image.

## 3 Creating Content

On closing the window, you return to the code screen where a part of the code is highlighted as "Type Content Here". In that area, you can put whatever you want to appear on the page, and

Type the page content in the highlighted area

it will conform to the formatting done in the previous windows.

There is even a spell-checker coupled with a dictionary to ensure you don't have any misspelled words going out to the world!

## 4 Other Options

If all you want is a basic Web page, you are all set, since your page is already set up. You can view it in a browser by pressing [F8].

You may, however, want to include tables, image place holders, anchors, etc. For all these, you simply need to click on the left pane, and a wizard will open. This will guide you through the process as before.

The wizards are pretty exhaustive, and very rarely will you require any further tweaking.

## 5 CSS

As your skills develop, you'll realise it is downright silly to give every image or text line individual formatting, especially if most of them have to be similarly

Create your style sheet using the wizards in the left pane

formatted. The rescuer here would be CSS (Cascading Style Sheets).

These are basically sheets that have 'classes', where each class represents a specific kind of formatting—for example, font type, font size, font colour, link colour, etc.—and all you need to do is include the style sheet referrer in the HTML page and use the classes before text. This, you will realise, will cut down your page size by at least half if not more!

You can have two kinds of style sheets—embedded and external.
