

A Typical Light Emitting Diode (LED)

Types of OLED

Creation of Light in OLED

1. Applied Voltage makes the current flow from the cathode towards the anode through organic layers. This leads to removal of electrons from conductive layer and introduces electrons in the emissive layer.

2. Removal of electrons from the conductive layer creates positively charged atoms called Holes which need one electron to form a stable atom.

3. The electrons from the emissive layer jumps to combine with the holes and in due process releases energy in the form of a light photon.

Construction of an OLED
