

Let Your Computer Chill

How many of us care about cooling? Meet someone who cares enough to risk running a liquid through his PC cabinet

Mithun Kidambi

Most of us aren't too bothered about the type of cooling equipment installed in our computers. As long as the fan doesn't drone too much and create a ruckus, we're fine with it. Also, overclocking one's computer and playing around with the latest and fastest graphics cards is a very geek thing to do. There are many among us who are happy seeing the screws on the PC cabinet tightly fixed: who'd want to meddle around with the motherboard and increase its working temperatures, bringing it close to levels that could result in a processor burn-out? Well, that's what separates the über-geeks from normal people: the urge to push the limits of their personal computers, to take its hardware to the next level and eke out some extra megahertz!

The Cool Guy

One such computer hack we came across is Sanjay Rao from Mysore. This third-year engineering student from Shree Jayachamarajendra college of Engineering, Mysore, has taken to developing better cooling methods for his PC with a vengeance. The passion started with a trip to a computer shop that assembled customised computers.

Sanjay says he spoke to the shop owner about the prospect of designing newer cooling systems.

"I partnered with a friend in this venture. I did the designing, while he went about collecting all the information and equipment. Most of our earlier designs were rejected because they were either too big or weren't efficient enough." But those rejections did not deter Sanjay, or Sunny as he prefers to be called.

"I wanted to make my own water block; I spent almost five months on research, but couldn't get satisfactory results," he says. Then, with the help of a friend, Sanjay got a DangerDen TDX
