Z87 Motherboards Test

UEFI BIOS

For the Haswell platform all boards that we tested had UEFI BIOSes, though each one was different in some way or the other. The MSI Click BIOS 4 implementation was noteworthy here: it has a main home page which is neatly segregated into various parts letting you quickly access settings, load profiles, flash BIOS among other things. The board explorer option is similar to the 3D BIOS we had seen in previous generation Gigabyte BIOS. It basically gives you an overview of your board and the components that can be tweaked in that particular area. Hardware Monitor allows you to set fan control speeds and monitor other relevant settings. The Click BIOS has different colour themes for different boards (yellow for MPower, red for Gaming series boards and blue for the mainstream ones). Navigation is a breeze and we did not notice any lag while using the mouse.

Gigabyte have completely revamped the UEFI BIOS and have thankfully done away with the 3D BIOS. The new BIOS looks quite impressive and you can customise the way it looks - set a background, add a different colour theme, set which settings come up front, go back to the classic BIOS design if you so want and so on. The homepage has the CPU status on the left and the system status on the right hand side with the BIOS details below and voltage, fan speed and temperature graphs up top. If you are not interested in these details, you can opt for a lower resolution mode which just shows the BIOS menus.

ASUS have taken most of the elements from the previous generation of UEFI BIOSes and it still is quite functional. ASUS have added some

additional features such as a list of all the changes made before you exit the BIOS along with the short cut keys that were present. It comes with a home page which gives you a quick view of all the necessary settings and statuses. You can even set XMP profiles and adjust fan speeds from the homepage itself. The look is different for the ROG boards and other boards, but basic navigational design is the same. The My Favourites allows you to add in your most commonly used settings under one tab for quick access. With different ASUS boards, you get different colours and the number of tweaking options increase.

Intel had impressed us with its UEFI implementation in the last generation and it continues to impress this time as well. Apart from the home page it has other menus and you can also customise your home page by selecting your preferred page. The cooling tab has some colour based on the values being depicted and some pages have further sub-pages making navigation seem a bit intimidating. But on the whole for someone who loves to tweak a lot, the Intel Visual BIOS has lots of options.

The ASRock, ECS and Biostar UEFI BIOSes are quite ordinary when compared to the ones above. Sure they have some design element associated with them, but little touches such as shortcuts, customisations, separate home pages is absent. You still have to navigate through the tabs to get to what you want. Biostar has the menu options on the bottom whereas the CPU and memory status on the left hand side. It seems as if Biostar is being different for the sake of being different without any thought process.
