

Camera Test**92**

We gathered cameras powered by a BSI Sensor costing less than 15K and test out their prowess

Motherboard test**98**

The Haswell platform is finally upon us and as always we help you select the best Z87 board for your needs

How cool is that?

This month we have 24 CPU coolers lined up for you from both liquid cooling as well as air cooling categories. Let's see which coolers will manage to keep your beloved processor completely chilled out!

Cooling is an essential part of all computer components and it's been playing a big role in computing since a long time now. But when you talk about cooling your computer, your computer's CPU is from amongst one of the hottest and most important components which needs to be cooled. Most people use the stock coolers, be it for Intel or AMD CPUs. But your CPU tends to get too hot on continuous full load when using the boxed coolers, especially in the Indian climate which is predominantly hot. In order to ensure the longevity of

your CPU, it is essential that you keep it as cool as possible. This is where aftermarket CPU coolers come into play. Not only do they provide lower temperatures but also headroom for overclocking your CPU and thus an option to squeeze out every bit of performance your processor may have to offer, which wouldn't have been possible with the silly stock coolers by any means.

Another scenario where aftermarket coolers provide advantage is in silent computing. Yeah, you may think that since your stock cooler has a higher RPM fan, it would be good for cooling. But the problem with stock coolers is that, not only are they bad in performance but they can also be

pretty loud, and you don't want to hear a sound like that of an airplane on your desk next to you. There are two types of coolers available in the market today which are air coolers and liquid coolers. So let's take a look at both the categories of CPU coolers and see which cooler will freeze your processor best according to your needs.

AIR COOLERS

Air coolers get directly hooked on to your CPU and have a heatsink with heat pipes running from the base of the cooler to the heat spreaders. Fan(s) are attached to the heatsink to cool the heat spreaders and this is how air coolers work. Some air coolers have a small foot-

print, but some are huge and require a lot of space around the CPU socket and also in your PC cabinet. In this category, we received 13 air coolers from the likes of Cooler Master, Deepcool and Noctua which belonged to various price brackets.

There are stock coolers and then there are stock cooler replacements which are strictly meant for no nonsense regular cooling without even crossing the border for overclocking demands. The Cooler Master (CM) Hyper TX3 Evo, is one such cooler. Equipped with a 92mm PWM fan, the CM Hyper TX3 Evo is the smallest cooler of the lot and also the cheapest, but it still has a fast fan which was only mildly audible outside the
