

Moto X spotted

Eric Schmidt was seen using the upcoming Moto X. We expect the new phone by Google to be highly customisable

Bugshot

Marco Arment, the maker of Instapaper and The Magazine, launches Bugshot developer app for markup of UI errors. <http://dgit.in/13WVbFT>

War of the BSI Powered Cameras

We gathered cameras powered by a BSI Sensor costing less than 15K and test out their prowess

Swapnil Mathur

swapnil.mathur@thinkdigit.com

The camera market is always flooded with new models, even before older ones are obsolete – a race driven by your need to have the latest and the greatest. However, there are now so many models from the same manufacturers, often sporting the exact same primary specifications, with only minor tweaks here and there to differentiate between models. What this means is that you can end up paying premium price for features you might not really need.

For this month's shootout, we gathered cameras that are under ₹15,000 (roughly), but with one key component: a Back-Illuminated (BSI) sensor. BSI sensors, as they are now known, are a new kind of sensor design which places the electrode wiring behind the photosites. Traditional CMOS sensors had this wiring right in the front, which reduced the amount of light effectively hitting the sensor, thus lowering their sensitivity. BSI Sensors do away with this block and effectively become more sensitive to light, yielding better images at higher ISOs. A good sensor is

the first and foremost spec you should focus on while buying a camera, so we put a bunch of these budget cameras into our shootout to make it easier for you to choose.

We've got entrants from Panasonic, Fujifilm, Nikon and Canon. Although we reached out to Sony, unfortunately, they were unable to supply us with review units of the specific cameras we asked for in time. We had a good mix of regular point and shoots, travel zooms and even ultra-zoom cameras in here, which was pretty exciting for us, comparing cameras across various categories.

FEATURES AND DESIGN

We have 10 point and shoot cameras that, on paper, are more or less comparable. However, after diving deep into the details the differences start cropping up. One perfect example of this is the image processor chips that go into these cameras. While we do know that these chips are responsible for offloading sensor data and also contribute to faster burst rates, what we don't know is exactly what other duties they perform. However, we do know there are subtle differences between chips and the algorithms they are infused
