Space is what we all want, be it in our house, our living room, our car, or even on our bed. We all desire more space because it lets us add more stuff. What we wish to convey is that, since we all use computers, tablets and cell phones, storage space has been one of the most important factors for buyers. This is perfectly plausible because the amount of content we come across daily is staggering. One of the most consumed type of content is multimedia and it requires a whole lot more space than documents or spreadsheets for that matter. The internet provides us with so much content, especially in the form of torrents that we are sure most of us have our hard drives filled with. So we usually go about buying a new one once the old one is completely filled. Pen drives just don't cut it when it comes to transferring huge files and this is where portable hard drives come into picture. Portable hard drives are different from regular external hard drives in the sense that portable drives don't require an external

power. Just take a portable hard drive, slide it in your pocket or bag along with a short data cable and you're good to go. This makes life easy for most of us who move to and fro between our work and home and always need to carry our important files along with us.

Due to the recent surge of the Dollar-Rupee exchange rate the price of components has gone up but nevertheless it's still not too late to get a portable hard drive at a reasonable price. And this test should help you make an informed decision. All the drives that we received for the test were USB 3.0 drives and one drive that

also had a Thunderbolt interface. We've performed quite a few tests to gauge the performance of each drive. And since most people have different capacity requirements, we've grouped the drives into two simple categories. The first category contains drives that provide up to 500GB of storage space. And for users who need more we have the other category consisting of drives ranging from one terabyte to two terabytes.

Without further ado, let's take an in-depth look at both categories so that it's easier for you to pick one that best fulfils your storage needs.

Take it Along

We put 16 USB 3.0 portable hard drives to the test to pick out the best ones from among them for your storage needs

500GB DRIVES

These portable drives are for people who have low to moderate space requirements. Ideally, 500GB drives are best suited for people who consume a huge volume of data and don't intend to store anything for long. We received six 500GB drives for the comparison and while testing them we were shocked at how fast some of the drives were, specially during real world transfer tests. The 4GB sample files transferred just under 9 seconds. Turns out that most of these drives have plenty of cache memory which in turn allowed
