

**WHY IS THE IPHONE 5C CASE SO HIDEOUS?**

This is something we, and many

other other people have been wondering. All that you can see through the croc holes is "non". What was Apple thinking? Such design mis-steps will, hopefully, be rectified: <http://dgit.in/wwnon>

**HOW TO SPOT FAKE GADGETS**

Sometimes things are not as simple as spotting the Nokla or Able type. And apparently counterfeiters sell \$700 billion worth of fake products every year. Here's an extensive list including fake Amazon Kindle chargers, Xbox controllers and a whole lot more: <http://dgit.in/wwfakez>

**SWITCHING FROM IPHONE TO ANDROID?**

If you are one those few people

in the world who weren't quite impressed with the iPhone 5S or 5C and don't see yourself upgrading your old iPhone this could be a good guide to help you cross over to the light. <http://dgit.in/zeswicher>

**FROM MONGOLIA TO MIT**

How does a student from a country in which a third of the population is nomadic, living in round, white felt tents called gers on the vast steppe, ace an M.I.T. course even though nothing like this is typically taught in Mongolian schools? Read the amazing story of the boy genius of ulan bator <http://dgit.in/wwgenuis>

# The iPhone 5S: What we like

The successor to the iPhone 5 is here. We take a look at some of the cool features of the new flagship from Apple.

- By Vishal Mathur

**B**efore the launch of the iPhone 5S, a lot was speculated about its hitherto unseen features. It was almost as if people were expecting the iPhone 5's successor to have the ability to fly into outer-space, repair the International Space Station, and land on the desk. On a more serious and realistic note, now that the phone has finally been unveiled, let's give you the lowdown on what kind of features it packs in. The iPhone 5s is exactly what we would expect, minor improvements and a couple of upgrades - no disappointments there. And of course, lest we forget, you can now purchase the phone in gold. So let's see what's new.

**A7 Processor:** The new A7 processor from Apple is something new and while Apple's claim to have gone 64-bit is true, the actual changes are far more intelligent and you'll have to delve deeper into to extract its secrets. What's special about the iPhone 5S is not just the processor, it's the architecture that's involved and more importantly, the ARMv8 instruction set. The instruction set brings about massive boosts in JavaScript and encryption performance and minor, but no less significant tweaks in a myriad of other areas. Overall, the performance gains are tremendous. The A7 is so powerful in fact, it seems to be giving Intel's latest Bay Trail atoms a run for their money.

**LTE support:** The iPhone 5s (and the iPhone 5c) support more Long Term Evolution (LTE) bands than any other smartphone in the world. Just as a refresher - LTE is a 4G data network technology standard that is now being used in the newer 4G networks globally. The iPhone 5s supports 13

LTE bands, which includes TD-LTE, the one we're using, or planning to use, in India. The 13 band LTE support means both new iPhones will support TD-LTE in Band 40. This is the same band that Airtel and RIL's Jio Infocom will use for the upcoming 4G networks in India. At least till we get any official confirmation regarding the support, either from the operators or from Apple, it's safe to assume that the iPhone 5s will be ready to get you connected to 4G networks in India if and when they arrive. The only flagship smartphone to do so right now.

**M7 motion co-processor:** Working alongside the new 64-bit A7 processor is the M7 motion co-processor that will take up some load on itself and free up the primary processor for other tasks. The M7 will handle data from the accelerometer, the magnetometer, and the gyroscope. The way the system is designed, the M7 will accept and interpret almost all the motion data and intelligently wake-up the A7 as and when required, leading to huge boosts in battery life. Or so Apple claims. Nike+ Move has already been updated to utilize the M7

motion co-processor. As with the Moto-X however, while the technology exists, it will be some time before apps can fully realize the potential of this technology. The option is there though, for those who need it.

**Biometrics:** The TouchID system that Apple has implemented is one of the biggest new features in the new phone. The idea behind the system is simple, authentication is becoming more and more of a pain in the neck and passwords are too cumbersome to type. The TouchID replaces your account password and phone unlock pin with a scan of your fingerprint. Access to your phone and iTunes store is now literally only a touch away. The sensor is essentially a grid of capacitors that map your fingerprints. Apple has also taken the trouble to place a sapphire crystal cap on the sensor to prevent it from getting scratched. A stainless steel activation ring detects when a finger is properly placed and wakes up the sensor when required. This is a very interesting feature that we hope to see more off in the near future.

**True Tone Flash:** Flash photography on cell phones has always been a nightmare thanks to how washed out the photos come out. However, the True Tone flash on the iPhone 5S shakes things up a bit by incorporating two flashes. What's interesting is that of the two flashes, one is warm and the other is cool. The camera examines the ambient light and then fires up the two flashes simultaneously, individually adjusting the power of each flash to provide a suitable colour tone. The flash is finally usable again.
