SPACE - THE FINAL #WTF

We explore the oddity of planets that shouldn't exist

Rohit Chetri
readersletters@thinkdigit.com

Multiverses. A hundred thousand million galaxies. Seventy sextillion stars. One sentient species capable of sophomoric puns. On one little blue dot. The sheer improbability of our planet's existence continues to impress us. And despite our attachment to this little blue marble we dream of other worlds. Hoping that someday we too, like the heroes of Verne and Clarke, may walk on strange soils under quixotic skies. So we search. And all we get from the universe is a giant plasma finger.

The search for planets, that may be similar to Earth, has thrown more curve balls than expected. Could the unusual discoveries from space be true paradoxes or (in karmic terms), is the universe screwing with us?

Exoplanets and Space Oddities

Man's first vision of a world beyond Earth first took shape thousands of years ago in ancient Greece when bearded men in surprisingly white robes promulgated that terra firma wasn't terra singularis ("unique" for the latin illiterate).

The idea germinated with the progress of scientific inquiry and found its

The Universe is playing a game of peek-a-boo with us.

way into heresy when Giordano Bruno, a Catholic monk, spoke of "countless suns and countless earths all rotating around their suns" in 1584. But already, in 1532 a 59 year old rascal called Nicolaus Copernicus published a theory 18 years in the making (read: Heliocentricity), that dethroned Earth as the centre of the

universe and ushered in the era of universal possibilities.

Fast forwarding a few centuries; humankind ventured out into space, landed on the moon, sent robotic envoys to its neighbouring planets and started telescopically vacuuming up the larger cosmos in search of more planets.
