it is also available for Linux, you can copy over your Windows install of a game in Steam to Linux, and then start the install on Steam for Linux. Steam will detect verify the files in the install directory and often it will just redownload a few dozen MB of data that corresponds to executables libraries and such.

Note that this will work even if you copy from someone else. If you have a friend who has a Windows (or Linux) install of Half Life 2, you can copy that over to your Linux (or Windows) install and have it ready to run in a jiffy.

On Windows, Steam games can be found in the SteamApps/ common directory inside your Steam folder (wherever you installed it). On Linux it can be found at ~/.local/share/Steam/ SteamApps/ common

should already know how to create a symbolic link with your eyes closed, and using just your left pinky.

Now that all your saves are in one place it is also possible to...

Sync your save games to your cloud storage

If you use a file sync tool like Dropbox you can even have all your save games automatically synchronised to your online storage by placing these links in your synced folder.

Some sync tools have a problem syncing when links are involved (for complicated reasons we won't go into here) so if your sync tool, or backup tool does not support symbolic links, there is still a way out. Instead of creating a link to all save folders in one location, move the save folder / file there, and then create a link back in the original folder.

Use a Windows install of a game to seed the Linux download

Games are, for the most part media such as videos, audio, images, and 3D geometry none of this content is actually platform-specific. There should be no reason why you would have to re-download all this data again separately for Linux and Windows. Unfortunately, no game store we know actually provides you game data files separate from the platform-specific libraries and executables.

If you use Steam though, there is a solution that often works. If you have a game installed on Windows via Steam, and

Utilities, tools and Resources

Lutris: Lutris is essentially a meta-platform that can manage games installed using numerous other platforms. It can be used to manage native Linux games, Steam for Linux games, Wine games, games installed on Wine through Steam, games running on an emulator for NES / SNES / N64, games installed for ScummVM, Dosbox, Frotz, browser-based games, if you can think of it, it can probably manage it. It can also sync your game setting online, and can sync games with your Steam library.

QJoypad: This nifty tool lets you configure what the buttons in your game controller do. Control the mouse with the analogue sticks, map mouse click to buttons, the directional pad to arrow keys, or whatever suits your fancy. Its a nifty way to play games that don't support a controller using a controller, or to generally use your control as a remote control.

GLXOSD: This is the closest thing you will get to Fraps on Linux. You might have to compile this yourself though, unless you use Ubuntu.

Bumblebee: If you have one of those laptops that switches between an internal Intel GPU and an NVIDIA GPU this tool is essential to manage that.

Unigine Heaven / Valley: These are some of the best graphical benchmark tools

available for Linux currently (outside of benchmark modes in games.)

PCGamingWiki: This is an absolutely brilliant resource for PC gamers. It offers everything from information about which stores offer a game, how to troubleshoot a game to save game locations. Just Google the name of any game followed by PCGW and chances are the first result will be to this wiki.

PlayOnLinux: It is an exceptional software for managing different Windows software installed on Linux via Wine, and even different versions of Wine. It includes profiles for many Windows games, so it can download and install the components that a game needs to run and create a shortcut to directly launch the game. It can even automatically download a game from Gog.com if you provide your credentials. While PlayOnLinux focusses on Games it can also be used to install software such as Microsoft Office or Photoshop.

Codewaeavers Crossover: It is essentially a commercial GUI for Wine, but its

If you quickly want to record a game and throw that up online, this one is a good bet.

creators actually contribute to the development of Wine, so if you can afford it do purchase it.

CastAwesome / SimpleScreenRecorder / Open Broadcaster Software: These tools let you record gameplay and (with some effort) even broadcast it via Twitch.
