

## RAM

The multitasking capabilities of a phone are further dependent on the amount of RAM it has. The more RAM your prospective phone has, the better it is. Of course, that doesn't mean you should just run after the device with the most RAM. Think about what you do on your smartphone, do you play a lot of

games on it, or do you just use a few simple apps and restrict your usage to calling?

The former would mean you need as much RAM as you can get, while the latter would mean that 1GB of RAM should be enough for you. A powerful processor doesn't automatically mean good perfor-

mance, unless your phone has enough RAM to feed it.

## Operating System

Perhaps the most important part of future proofing your smartphone is through the OS, especially on Android phones. Ideally, you should buy a phone that runs on the latest version of Android, if not, the version just before the current one is also fine. This is especially important for phones that come with their own UIs, since OEMs often slack off on updates when they have their own UIs. You should also ensure that the company you're buying the phone from has a good track record for providing updates on time. Motorola for example, is without a doubt the best at this, while Samsung is good with updates for its high-end devices but neglects mid-end to low-end devices unless they were newly released.

You can also make a choice based on operating systems. If you like using a lot of different apps, then you're definitely going for Android or iOS. On the other hand, if you're a basic user, then Windows

is a very good looking and quite a capable operating system.

## UI

With saturation on the hardware side, almost every company is going for its own UI nowadays, in order to achieve product
