

Wolfenstein is back!

Did you like Wolfenstein: New Order? Then you should try its prequel! - <http://dgit.in/1EZ0eaI>

Ask anything!

MyITReturn, a popular e-filing platform, has launched an 'Ask a question' feature on their mobile app: <https://myitreturn.com/>

DO

and current values, you need to determine whether it's more voltage you need or more current. If it's current, arrange the cells in parallel (<http://dgit.in/1Ap5ABa>) and tape or solder the cables accordingly. If it's voltage that you need, arrange the cells in series and tape or solder accordingly.

Double-check you're the voltage and output with the multimeter and if you're satisfied, proceed to the next step.

Step 2

Attach a diode to the positive end of the bank of cells that you've created. This is optional, but necessary if you're not sure of the voltage of your solar cells. If you have a car charger, follow these steps:

1. The pointy bit at the end of the car charger is the positive terminal and the metal springs on the side are the negative terminals.
2. Hook up the solar cell bank to these terminals accordingly. You can simply use insulation tape to do this.
3. If you only have a USB cable:
4. Double check all your calculations first. The solar cells that you used will normally not be powerful enough to cause damage, but it's better to be safe.
5. Attach the positive end of the cable to the red wire and the negative to the black.
6. Place the solar cells in sunlight and examine the voltages with a multimeter. If everything is good, you can plug in your phone.

Place the solar cells in direct sunlight and plug in your phone to the car charger. If your voltage and current calculations are correct and there was no issue with your wiring, you will now have a working solar charger. It's that simple! 

This charger will work as a universal USB charger as well. You can hook this charger up to a window and attach it to a power bank to charge it if you so desire.

Your solar charger is this easy to make. The cell here is for representative purposes only. You'll need at least 4.5 V to make use of this charger

A multimeter is absolutely essential for measuring the power of a solar cell. As you can see, even in bright daylight (mid-afternoon), the voltage is minimal from such a tiny cell
