DO

OpenTrack is the tool of choice for enabling HeadTracking.

You need to fine-tune your response time with the curves settings in OpenTrack

Here's a snapshot of the SplashTop Streamer that should be running on your PC

6. If you have a phone and router with wireless AC support, you needn't tone down your resolution, but if you don't, bring down your desktop resolution to 1280x800 or lower.
7. Run Splashtop Streamer on your PC and run the app on your phone.
8. Install OpenTrack from <http://dgit.in/1SpIINw>
9. Fire up your head-tracker's LEDs and position your camera as instructed in the head-tracking tutorial that you dug up in SKOAR.
10. Depending on the type of game you're playing, you'll have to set OpenTrack to run in either "TrackIR" mode or "VJoy" more. The former is perfect for flight sims and other games that support head movement in-game, the latter is useful for all other games as OpenTrack converts all movement into joystick input that can be assigned in-game.
11. Run the game.
Voila! You're now gaming on an Oculus Thrift!

HMD (Expensive)

If you're willing to spend a bit more money, you can build a much better alter-

native to the Rift. The previous method works great if you're on a really tight budget, but suffers from lag issues and is limited by your Wi-Fi router and phone.

The alternative is to spend money on a 7" SVD display with adapter (like this one: <http://dgit.in/1AkANWz>). An SVD connector

A Delanclip, the perfect alternative for those who'd rather not build their own clip.

is something like a DVI connector that's used in smartphones and tablets and you'll need an adapter to add at least D-Sub support. This will cost you between ₹6,000 and ₹8,000 depending on the model of LCD that you buy.

What you have to do is first purchase the display, build an Oculus Rift style housing (similar to a Google Cardboard

design, but designed to accommodate the larger 7" screen.) You'll also need to use larger lenses with at least 5x magnification for the housing.

Attach the head-tracker to this housing as you did for the budget HMD.

After that, just assemble the LCD, power it up, plug it into the D-Sub port on your PC and set it up as a secondary display that mirrors your PC. The resolution is limited to 1280x800, but it's more than enough for a thrift.

Run the games using SBS 3D and configure as described earlier.

Note: You can also purchase a ready-made TrackHat from www.trackhat.org if you can't or don't want to build your own headset. Another option is to purchase or build an EDTracker from www.edtracker.org.uk. EDTracker is an Arduino based headtracker that has the advantage of being far more precise and hassle free than the original, infra-red LED based design, albeit at a higher cost.

Warning: Using 3D glasses and / or head-tracking can cause motion sickness so if you're new to it, make sure you have a bucket or an air-sickness bag beside you.^[1]

We're using SplashTop here and as you can see, there's no discernible difference in image quality between your PC and your phone.
