

So many atoms

There are 8 times as many atoms in a teaspoonful of water as there are teaspoonfuls of water in the Atlantic ocean.

Let's go to Titan

Humans can literally fly by flapping their wings on Titan due to its thick atmosphere and low gravity.

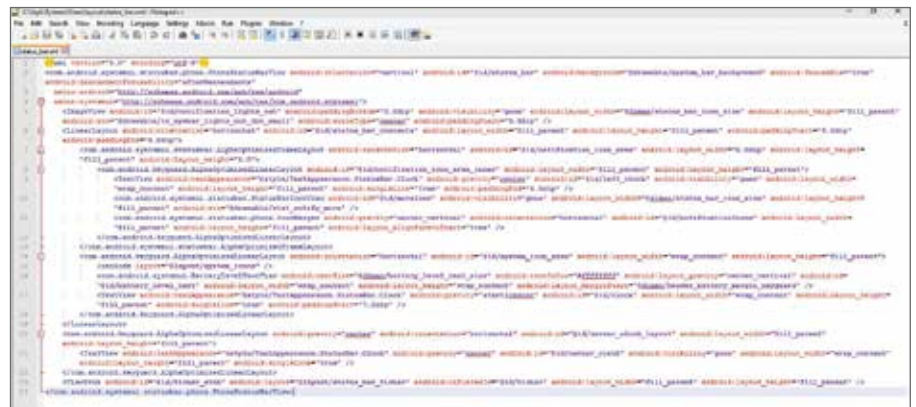

framework-res.apk and apktool if SystemUI.apk. Now that you have installed the resources, you can proceed with decompiling the apks.

To decompile an apk, you need to use the following command `apktool d SystemUI.apk`. You can use the same commands to decompile any other apk.

Replacing icons and other UI elements

After decompilation, a new folder bearing the apk name will be created. Browsing the decompiled folder should reveal multiple folders containing files that make up the apk. These files can later be used for further customisation. Editing images isn't difficult at all. The original UI elements such icons, sliders, and separators can be successfully replaced with customised ones as long as all you retain the original filenames. The best part is that decompiling or signing the apk isn't required if you are only planning to replace the icons and png images. You can open the png images on either GIMP or Photoshop and edit them, while ensuring that the original dimensions are retained. Now, open up the new apk in WinRAR and drag and drop the edited pngs into it. This should open a window to select the compression methods. This will only work if the "Store" compression method is used.

When it comes to .9 png images, you have to decompile and edit them using either the above mentioned Draw9patch tool or any other image editor. After saving all images, navigate to "SystemUI/res/drawable-hdpi" where you can access all system icons. Do note that you need to maintain the original resolution and dpi of those icons, to avoid any issues. An Recognized Themer named Yorzuha has created a handy guide on creat-

Use Ctrl+F to find the right parameter

ing and editing 9 png images, which is worth referring: <http://dgit.in/9PngTut>.

To read an extensive tutorial on how to replace icons on Android devices, refer to the following thread: <http://dgit.in/AndrIconTut>. Just remember that the process of replacing UI elements is deceptively easy. The only challenging part is editing the elements due to the sheer volume and tedium of the process.

Changing text colour

Text colour can be modified by editing xml files. To do this, browse to "SystemUI/res/layout", which is a location housing xml files that define the position, colour, text, and almost every other UI parameter. Finding the specific code defining text colour can be a time consuming affair due to the sheer volume of text. Here are some of the places where you can find and edit text colour for your theme: <http://dgit.in/1HyXjgR>.

Change system text settings requires editing multiple xml files. This process involves extensive use of the Ctrl+F command to search for instances mentioning the colour parameter. The following guide is a great resource to attain a firm grasp on the basics of editing xml files pertaining to system text settings for building or editing your own theme: <http://dgit.in/SysTextSett>.

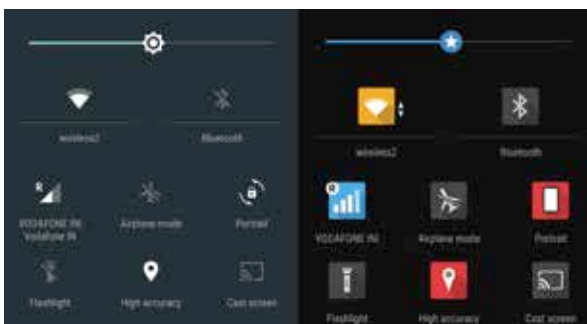

Recompiling

Now that you have edited and made required changes to your custom theme, you are ready to recompile or build the files into an apk. To build an apk from the files obtained through the decompiled Sys-

temUI.apk, enter the following command `apktool b SystemUI`. The recompiled apk file of the entered folder will be created in the "dist" folder inside the decompiled folder. Before using the apk file, you need to sign the apk. To do that, open the original apk in WinRAR (open WinRAR and drag the apk file into the window). Drag and drop the following two files "AndroidManifest.xml" and "META-INF" folder into the dist folder. Open the newly built apk in WinRAR and drag and drop the resources.arsc into the same dist folder. Now, open the new apk in WinRAR and drag and drop these three files into the window. This leads to a list of compression options. It is very important to choose "Store" compression option. Failing to do that might send your phone into a boot loop when you restart.

Once you're done with the above-mentioned steps, copying and pushing the new files to your phone is the final step. This can be done using the adb command `adb push C:\Android\Apktool\SystemUI\dist\SystemUI.apk /system/priv_app`. Alternatively, you can refer to the following tutorial replacing apps on your phone <http://dgit.in/AppRepTut>.

You may encounter many tutorials based on custom themes. This article serves as a primer for the basics of the process. Using this knowledge, you seek out more specialised guides and tutorials pertaining to editing individual sections or components such as the status bar, Settings app, notification bar, etc. Those conversant with the Smali programming language can begin editing Smali files, which is usually the domain of advanced themers and developers. **[4]**
