

Rosetta Code is an online programming chrestomathy which has a compilation of common programming algorithms in almost all programming languages.

Project Euler is a website with a mathematical approach to programming. It features numerous computational problems that can be solved using a computer. Though it is math-intensive, some problems don't even require a computer. But it's still a great way to practice programming; especially if you plan on going into mathematical projects. You should be able to solve at least 10 - 15 initial problems even if you don't have a background in mathematics. These aren't the only websites, there are tons of other websites such as w3schools or dream-incode for help with projects. Additionally, stackoverflow.com is useful when you are stuck somewhere and unable to think of a solution.

Understanding the skill requirements

Building projects isn't just about writing and compiling source code. Instead, it entails building a complete environment where your application will interact with various entities around it, such as users or other devices. However, it isn't necessary for a project to interact with some external entity at all times. It is still essential to master these skills besides programming. These involve usage of various APIs (Application Programming Interface), building user interfaces, database connectivity and maintenance etc. If you learn a skill that is in-demand and is uncommon in the software industry, it might improve your employment prospects.

Even after the completion of a project, testing and debugging is an uphill task. It's a myth that testers don't code. Even if you plan on delving into software testing as a vocation, sufficient knowledge of programming languages and their implementation is essential. Testing is a major part of projects and takes place before deployment. It is a sought-after asset since it requires good observation, analytical and com-

UIADI provides an Authentication API using Aadhar ID and demographic/biometric information.

munication skills to interact with the end user.

Developing ideas for the project

Ideas rarely happen to strike out of nowhere. They are mostly inspired by practical problems or the needs created in day-to-day life. They can consist of solutions that improve the quality of life and technologies that simplify common tasks. If you are struggling for a project idea, these tips may come in handy.

There are a lot of websites that can help you with the decision. Programming subreddits and other forums often host discussions regarding new projects and technologies. Frequenting such forums is a smart way to put out project ideas for feedback from fellow programmers.

Google Summer of code has some very good projects to get some inspiration.

Additionally, you can refer to Google Summer of Code (GSoC) archives for a host of ideas recorded since its inception. GSoC is a project that encourages students to code. It is held annually during summers. Although this programme is only open students, the ideas showcased there are inspiring and can help budding programmers to develop projects better.

Join an open source project:

An open source project or software is a freely available software along with its source code. The source code is available to everyone and can be studied, changed, and redistributed by anyone. A major advantage provided by open-source software is that it is constantly improved with collaborative efforts of participating individuals. Contributing to the open source community is considered to be a good practice.

Numerous projects such as Firefox, Android, and OpenOffice allow inputs from the community for developing and improving their ecosystem. It should be noted that coding is not the only way to contribute to the open
