

Mind boggling

A prosthetics manufacturer has developed a mechanical limb that can be controlled mentally:

Wait, what?

An IAF fighter jet managed to land on a highway as part of a new landing procedure:

the exhaust is slow. This way, there will always be enough air in the case to carry heat away. Negative systems are quieter as well. While implementing this system, ensure that there's enough ventilation at the right positions for intake, while ensuring that radiators get targeted intake.

POSITIVE PRESSURE – MORE IN, LESS OUT

More inflow of air means better cooling. Positive systems are recommended only if you can keep a periodic check on dust accumulating inside the case. The cooling performance exhibited by this setup is slightly better than negative pressure systems. Moreover, the abundance of intake causes build-up of internal pressure, which aids exhaust in turn.

NEUTRAL PRESSURE – BALANCED IN AND OUT

A Neutral system is almost equivalent to a system running with the side panels open, which is otherwise very difficult to imple-

JIXOS

About his creation

JIXOS is a Windows-based Open Source operating system developed in Batch. The operating system was programmed in four days and took 2,269 lines of code. It runs best on Windows XP (32-bit) along with the Java Development Kit (JDK) installed. The OS is also compatible with Windows 8 and 7. The new version of JIXOS now includes the DOS game, *DOOM*. The inspiration to build JIXOS was solely his love for programming.

About the creator

Saarisht Thaman, currently in Class 10, has been learning to code since the very young age of 11. By reading through many books, the first programming language that he learned was QBasic. Since then, Saarisht went on to learn more programming and scripting languages such as Batch, HTML, C, C++, JAVA, Pascal, BASIC, PHP and Javascript. Saarisht recently developed a simple *Arkanoid* game and has gained a keen interest in Arduino programming.

ment. The open panel setup is hazardous for many reasons starting with air being static.

6. ADJUST YOUR SETTINGS

Adjust the fan speed for normal as well as heavy use. The noise is linked to air turbulence generated between the blades and grille, and can be reduced by lowering fan speed.

A good airflow system keeps the machine from reaching high temperatures under medium load. However, if overclocking or processor/GPU intensive applications are involved, it makes sense to go for a more effective and expensive cooling system. Hopefully, this primer in airflow management will help you select the right components and design your own cooling setup. 

CABLE MANAGEMENT

And why it's important!

This is important because cables invariably tend to obstruct airflow unless managed optimally. The best way to manage cables is by routing the biggest and thickest cables initially, which happen to be the motherboard and CPU power cables. It also helps to fold, tie, and put away unused PSU cables.

Most modern PC cases are designed with enough room at the back of the motherboard tray to facilitate routing cables through the gap between the motherboard tray and the side panel. The side tray behind the motherboard bears multiple hook points to accommodate cable ties, which can be used to streamline more cables. Just make sure you avoid overlapping the cables otherwise closing the side panel of the case can be a problem. If you insist on ensuring a really clean cable management job, a modular PSU will go a long way in making that possible.
