

3) CONNECTIVITY WITH WINDOWS IS A PAIN

Apple iPhones seamlessly pair with Apple's own macOS, but not with Windows OS. My Phone app on Windows has evolved to be a useful tool, especially on Samsung phones and that convenience is what we sorely missed after switching to an iPhone. If you use Windows PC, that's something to keep in mind. Not just wireless, but even wired connectivity is very restrictive. Simply moving a few simple videos from your Windows PC to your phone is a task. You will need to install iTunes on your PC and spend some time looking up your files on the phone.

4) GOOGLE APPS TAKE A BACK SEAT

This is one obvious peeve point. It's second nature for Android users to depend on automatic Google Drive backups, Maps and Google Photos, and it takes some time and effort (and money) to switch to iOS alternatives. The dialer app for instance doesn't show probable contacts we are dialling when we have partially dialled a few digits. The contact name appears only when you key in the entire number. Thankfully most of the popular Google apps work fine on iOS, but a few like Google Rewards are still missing.

Subscription to Google services like YouTube premium subscription is more expensive on the App store.

5) NO CALL RECORDING

Apple iPhones do not support the call recording feature, which is a very popular feature in India. If you are someone who often records calls for personal or professional reasons, this is something you should keep in mind. Even on most Android phones, call recording isn't as seamless as it used to be. Still, Samsung phones support the option for auto call recording and many others support call recording with a voice prompt. Apple doesn't support Call recording on iPhones because it is illegal to do so in certain markets.

6) NO DIRECT CELLULAR VIDEO CALLS TO ANDROID PHONES

You can do FaceTime with other iPhones on the cellular network, but you must know that there is no option to directly video call Android phones. You just can't simply convert an ongoing voice call to an Android phone to a video call. You will need to disconnect and do a video call using third-party apps like WhatsApp. This is not an iPhone problem per se, just something to keep in mind if most of your family and friends are using Android.

7) VOLUME CONTROLS AREN'T AS ELABORATE

While I am working from the office, I usually keep the

media volume minimum. This prevents any accidental video in an app feed from blasting off accidentally. That's easy to do on Android phones that let users separately address System Volume, Media Volume, Ringtone Volume and Notification volume directly from the volume buttons without diving deep into settings. iOS on the other hand is missing such elaborate volume control. Volume for notifications, media, and system sounds goes up and down simultaneously. You can keep the ringtone volume separate, but then you won't be able to adjust it using the volume buttons.

8) VERY DIFFERENT FILE SYSTEM

The file system for iOS is very different from Android. Apps are responsible for their own files and you can't simply open a file manager and navigate to the files you downloaded in the browser. Sharing files between apps is also not seamless. For instance, if you download a video in safari, you can't automatically play it from your gallery. You will have to go to 'Downloads' within the Safari options menu and then share that specific video with the Photos app. Only then will the downloaded video show up in the iPhone's gallery.
