Smartphone specifications that are actually misleading

Trust them always...
Maybe not?

Deepak Singh | deepak@digit.in

It shouldn't come off as a surprise that specifications can often be misrepresented and misunderstood. The intention isn't always to mislead customers but sometimes the truth gets muddled up when overzealous marketing teams try to oversimplify technical details.

More often than not, this doesn't result in consumers losing out on much. At the same time, if you are an enthusiast that doesn't mind sifting through technical details and wants to understand your phones better -

here are a few interesting facts that we are sure you will find exciting!

CAMERA SENSOR SIZE

The bigger the camera sensor, the more light it can gather - and that indeed helps improve the quality of images and videos you capture. However, as weird as it may sound, you must know that sensor size doesn't denote its actual size.

For instance, contrary to what is shown in the image above, the 1-inch sensors that have surged in popu-

larity on drones and smartphones don't have any dimension - length, breadth, depth or the diagonal of the surface - that measures 1-inch. The actual dimensions of Sony 1-inch sensor used on the Xperia Pro-1 measure 13.3 mm x 8.8 mm which is nowhere near the 25.4 mm or one-inch mark.

The thing is that it's conventional to denote sensor size in terms of vacuum tube sensors that were earlier used in cameras and are now obsolete. To calculate sensor size, the diagonal measurement of the sensor surface area is multiplied by $3/2$. This results in all sorts of odd sizes like 1/2.5-inches and 1/3.3-inches which aren't actually true.

This is why Sony calls its sensor a 1-type sensor and not a 1-inch sensor. Smartphone OEMs, however, are not always as forthright.

3X OPTICAL ZOOM IS NOT ACTUALLY 3X

For actual zoom, you will need the lens on the camera sensor to move back and forth. Some smartphones did experiment with the concept but

it turned out that consumers didn't crave additional zoom at the expense of pocketable design. Modern phones use an optical trick for magnification.

Your phone switches to a different sensor with a telephoto
