

“xrOS” On The Horizon

Reports and insider information are suggesting that the operating system for Apple's new AR/VR headset has been renamed to xrOS or Extended Reality OS. For a long time, it has been rumoured that Apple has been secretly working on an AR/VR headset of their own. This is however in contrast to the current CEO - Tim Cook's statement that people shouldn't be encouraged to live their whole lives in a virtual world. While we do agree

that he was targeting some other company's marketing campaign * coughs * Meta, we don't think that Apple will fully move back on its word.

We think that Apple will be building a device which puts AR first rather than putting VR first. This will allow Apple to integrate their services more seamlessly with the real world and expand the capabilities of the Apple Ecosystem. Earlier, the same operating system was called “realityOS” or “rOS” but according to Mark Gurman from Bloomberg, Apple changed it to be “xrOS” so that it feels like a less generic name. Apple has filed a trademark for the same under a company named Deep Dive LLC.

“Hey, GitHub!” Is The New Keyword Now

We all have grown accustomed to using Siri or Google Assistant by calling out their respective “trigger words”. Just one command like “Hey Siri” or “Hey Google” is enough to trigger the virtual assistant and make it listen to your further commands. Well, GitHub is developing something similar in their labs and according to them, it's going to eliminate the use of keyboards for programming.

We all are familiar with GitHub copilot - your AI pair programmer. They launched it around a year back and it has received a tremendous response since then. That thing literally auto completes the whole function or a whole code block for you and it's next version is coming now. Introducing “Hey, Github!” - your AI voice controlled pair programmer who will write out all the code for you just by voice commands.

Using AI To Generate SQL Queries?

After the rise of ChatGPT, as developers, it feels like our jobs might be in danger yet again, and now it's because of a completely different AI tool. Say hello to AI Query. This little bad boy can generate SQL statements

from scratch using AI. Yes, you heard that right. Just give a regular english sentence as an input - something like - “Get shipping data for the customer with ID 10” and it'll throw a SQL statement right back at you. Not just this,

it can even do complex joins, WHERE clauses and much more. To use it, you need to define a schema for all the tables in your database and that's pretty much it. You can use it to just generate raw SQL statements for pretty much any transaction you like. As of right now, AI Query is in beta. You need to sign up and get accepted to play with it but later, it will move on to a paid subscription model. You can check out AI Query at:

<https://www.aiquery.co>
