

UberEats enhancing its privacy

The food delivery app UberEats has just released a feature in their app which would make privacy focused people breathe a sigh of relief. "View as delivery person" will let users see and browse through all the information that gets shown to the delivery person who usually delivers your order. The addition of this new feature will definitely provide the customers with extra peace of mind by enabling further transparency between the customer and the company.

The main crux behind this whole feature is that as soon as you'll place an order, you'll get prompted to see a page which will outline all the different data that the delivery person has. According to UberEats, the delivery person only has the approximate location of an order when they receive the order and when they complete and deliver the order. If they choose to accept the order, then and only then, the client's Name and, etc. will be shown to the driver. This screen will also show and list out all the data that the driver WILL NOT have like the user's payment method, phone number, etc. This feature is slowly being rolled out in the US and Canada right now and is expected to be released worldwide in a few months after testing.

Chromium gets Rusty!

Dana Jansens, a team member from Google's open source project Chromium has announced via a blogpost that Chromium will get additional functionality to import and use third-party Rust based extensions. "Our goal in bringing Rust into Chromium is to provide a simpler (no IPC) and safer (less complex C++ overall, no memory safety bugs in a sandbox either) way to satisfy the rule of two, in order to speed up development (less code to write, less design docs, less security review) and improve the security (increasing the number of lines of code without memory safety bugs, decreasing the bug density of code) of Chrome," explains Jansens.

Moving forward, if this gets implemented correctly, it would be a big thing for both Chrome and its open source cousin, Chromium. Till now, the only way to develop extensions was to write them in plain HTML, CSS and JS and then ship the whole bundle. We all know that JavaScript is not particularly known for its memory safety and type safety and hence the introduction of Rust into the picture might just stir things up.

Also, around 70 per cent of issues in the Chromium browser itself are memory issues. Hence, Rust, when used correctly can replace all of the leaky C++ code with a code that can guarantee memory safety.

GoldenEye 007 Just Got Revived

If you're a 90s kid then you must've played GoldenEye 007. That game defined an era of its own and the best part is that the game still has active players to this day! This game was released in a period when computers were not all too powerful to handle 3D graphics and complex physics calculations. Hence, GoldenEye 007 got released with the OG blocky characters and low resolution textures. After more than 25 years of its release, the game is now getting a re-release on modern consoles.

Nintendo Switch and Xbox versions of the re-released game are hitting the markets on January 27th.

The game will be launching through Xbox Game Pass and Nintendo Switch Online + Expansion Pack. While team green will be able to play the game as a part of the Xbox Game Pass, people

from team red will have to buy an extra \$50 subscription to the Online + Expansion Pack and then they will be able to play it. The Switch version will have multiplayer features, 4K upscaling and even a widescreen mode to do away with the 4:3 aspect ratio. Game Pass users will only have 4K upscaling support on their side and a local multiplayer mode. [cd>](#)
