

## Expert Talk

A lot of the software (from Formula E cars), to be perfectly honest, is not far away. The things that we learn from Gen3 cars, we can implement them for efficiency and for safety. There are many different applications of the software (from the Gen3 Formula E cars) that we are using in modern EV cars.

**JAMES ROSSITER**  
Team Principal - Maserati MSG  
Racing Formula E Team

The first topic to work with there is mainly around the software. So, the strategies to do with how the energy is used during the races in these cars is particularly relevant and something that will transfer (into the road cars), possibly quicker than you might think, within two-three years possibly.

**LEWIS BUTLER**  
Technical Director - Mahindra  
Racing Team

There are a few key systems on the car - the regeneration system has a number of elements to it, so brake by wire is the most important one. So the driver's (in a Formula E car) foot, when he presses the brake pedal, is not actually pushing the hydraulics systems on the brake. He presses his foot (on the pedal), and the potentiometer tells the computer the brake force, and then the computer decides whether we have friction braking or regenerative braking, depending on the temperature of the battery or the state of charge of the battery. (This is) because you can't always regenerate a hundred per cent all of the time. So, the work we're doing on this regeneration system, that's the key technology, and that's the stuff that is going back into the road car program.

**MARTYN SMITH**  
Nissan Racing Team
