

iPhone 14 (left), Pixel 7 (middle), Galaxy S23 (right)

is adept at clicking fantastic portrait shots with good colour, detail, and edge detection. The Pixel 7 doesn't have a telephoto camera but can take 2x digitally-zoomed portrait shots, which the iPhone 14 cannot do. However, these 2x shots look artificially sharpened and the edge detection is quite messy.

Since the Samsung Galaxy S23 has an extra telephoto lens with 3x optical zoom, its zoom capabilities far exceed the iPhone 14 and the Pixel 7. The telephoto images are detailed and vibrant with good dynamic range. You can zoom all the way to 30x digitally on the S23, however, the shots aren't detailed at 30x, but if there's text in the picture, it is surely readable. Additionally, digitally-zoomed 10x shots are surprisingly detailed and usable, so that's an added bonus.

## Ultrawide

All three phones – the Samsung Galaxy S23, Pixel 7, and iPhone 14 – have ultrawide shooters. By default, the Pixel 7 has a narrower FOV (field of view) than the Pixel and Samsung. Again, all three flagships deliver some stunning ultrawide images packed with quite a bit of detail, however, the Pixel 7's ultrawide camera does edge out a bit in terms of overall detail. Samsung once again continues the trend and clicks brighter ultrawide images than the other two phones, so the highlights can sometimes be overexposed on this phone.

Ultrawide barrel distortion is negligible on all three phones – which is expected given their price and positioning in the

market. In most shots, Samsung and Pixel does well in maintaining dynamic range, there are some instances when

Samsung overexposes highlights. However, the iPhone 14 struggles a bit in comparison to the other two when faced with tricky lighting conditions, as it crushes detail in the shadows.

## Low light

Moving on to low light photography,

there are some key differences in the capabilities of each phone in low light. Generally, pictures out of the Samsung Galaxy S23 are the most bright. It does a good job of exposing the highlights so they don't appear too blown out even in low light and there's a good level of detail present in the shadows. The Pixel 7 also clicks great low light images with the least lens flare of all three phones, but if you pixel-peep (pun not intended), you will find the detail to be a bit soft, especially in the shadow areas.

The iPhone 14 clicks decent low light images, but unfortunately, we found that a lot of detail was missing in the shadows and the pictures also

looked artificially sharpened at times. The iPhone 14 also applied a strange blue tint in some low light photos and it wasn't present when we clicked a photo with the other two phones in the same setting. If you want to capture human subjects in low light, both the Samsung Galaxy S23 and the iPhone 14
