

iRevolution Unfolded

Looking into the future of Apple's iPhones with the help of AI

Haptic Buttons on iPhone:

Apple has been exploring the idea of haptic buttons that provide a more realistic, tactile sensation when interacting with the device. This would mean the traditional mechanical buttons on an iPhone could be replaced with touch-sensitive areas, providing users with a more streamlined design and better water and dust resistance. Apple's current haptic feedback implementation suggests they may bring this technology to future iPhone models.

Foldable Display

Foldable display technology has seen rapid growth in recent years, with companies like Samsung and Huawei already offering foldable smartphones. Apple is no stranger to this trend, and there have been multiple rumours and patent filings suggesting the development of a foldable iPhone. Apple's expertise in hardware and software integration would ensure a seamless user experience in such a device.
