

ourimeter, follow the manufacturer's instructions for installation and setup.

Step 2: Configure software settings

Select your colourimeter from the list of available devices and configure the settings according to your needs. Here are some common settings to consider:

- **Display type:** Choose between LCD, LED, or OLED, depending on your display technology.
- **White point:** For most users, the standard D65 (6500K) white point is recommended. However, you may choose a different white point based on your specific requirements or preferences.
- **Gamma:** The standard gamma value is 2.2, which is ideal for most scenarios. Some workflows may require a different gamma value, such as 1.8 for print work.
- **Luminance:** Aim for a luminance value of 120-140 cd/m² for typical office or home environments. If you work in a particularly bright or dim room, you may need to adjust this value accordingly.

Step 3: Place the colourimeter on your display

Position the colourimeter on your display as per the manufacturer's instructions. Typically, it should be placed flat against the screen with its sensor facing the display.

Step 4: Initiate the calibration process

Start the calibration process by following the prompts within the software. The software will display a series of colour patches, which the colourimeter will measure. This process usually takes several minutes to complete.

Step 5: Create and save the ICC profile

Once the calibration is complete, the software will generate an ICC (International Colour Consortium) profile. This profile contains the data necessary for

your computer to adjust the display's output for accurate colour representation. Save the ICC profile with a descriptive name, such as the display model, date, and calibration settings.

Step 6: Set the ICC profile as the default

For Windows:

1. Open the Control Panel and navigate to "Colour Management".
2. Select your display from the "Device" dropdown menu.
3. Check the "Use my settings for this device" box.
4. Click the "Add" button and browse to the location where you saved the ICC profile.
5. Set the newly added ICC profile as the default by selecting it and clicking "Set as Default Profile".

For macOS:

1. Open "System Preferences" and navigate to "Displays".
2. Go to the "Colour" tab.
3. Click the "+" button and browse to the location where you saved the ICC profile.
4. Select the newly added ICC profile to set it as the default.

Calibration Maintenance: Staying Consistent

Display calibration is not a one-time process. Over time, display characteristics can change due to ageing and usage, causing colour shifts and reduced accuracy. To maintain a consistently calibrated display, it is recommended to recalibrate your display every 1-3 months or whenever you notice a significant change in colour representation.

Additionally, if you work with multiple displays, it's essential to calibrate each one to ensure colour consistency across your entire workspace.

The Path to Visual Perfection

Mastering display calibration can significantly improve your visual experience and optimise your workflow. By investing in the right tools and following the calibration process detailed in this guide, you'll ensure your display is always at its peak performance, delivering accurate colours and stunning visuals that meet your highest standards. Embrace the power of display calibration and elevate your work to new heights.
