

AI finds a planet 11 billion kilometres away

Looks like AI is giving even astronomers a run for their money; AI has even found a new planet 11 billion kilometres away!

Ichha Sharma | feedback@digit.in

When we speak about AI, the majority will think generative AI applications like ChatGPT or Midjourney, or personal assistants such as Alexa and Siri. However, the journey of artificial intelligence has progressed by leaps and bounds where we are talking about using machine learning and artificial intelligence to regenerate a human heart, produce autonomous vehicles and now, extend the technology further to even discover a new planet. That's right, AI has recently contributed to discovering a new planet.

A team at the University of Georgia confirmed that artificial intelligence

played a fundamental role in discovering a new planet outside our solar system. This can be considered as a pathbreaking system in discovering new exoplanets which can help in identifying new planets by just utilising the protoplanetary disks.

The basic understanding of this system is that AI helped in oper-

ating simulations to locate the exact periphery of the planet. However, the system is extremely intricate and complex and has taken the contribution of AI in Astronomy to the next level.

AI planet discovery

Jason Terry, a doctoral student at the UGA Franklin College of Arts and Sciences exclaimed "This newly-discovered planet increases the already extensive collection of over 5,000 exoplanets identified beyond our solar system."

The technology is commendable for the abilities artificial intelligence is offering to astronomical and space studies. Until now the newly discovered planet was hard to identify because it was orbiting 75 astronomical units away around its star, hindering the astronomers' attempts at accurately gauging it.

As of now, astronomers have discovered 5,000 exoplanets and as the technology improves the use of AI in identifying celestial bodies is only going to increase. The mission of discovering unknown and harder-to-detect planets has expanded with technology upgrading and revolutionising itself, thanks to AI.

How does AI help in planet discovery?

The Astrophysical Journal recently published two papers which gave insights about how machine learning has been contributing to the discovery of planets beyond our solar system in outer space. The technology helps in identifying the faint signs in dense dust disks that form planets which eventually develop young stars.
